Detailed steps of evidential reasoning
Step 1: Obtain attribute-level evidence
Continuous inputs: interpolate beliefs, reliability and weight between adjacent interval centers.
Binary inputs: look up the matching interval.
Step 2: Weight and discount evidence
Use rule weights and rule reliability to form the weighted evidence for each selected attribute.
Step 3: Fuse evidence
Aggregate the seven attribute-level belief distributions using ER-Rule and normalize the fused beliefs.
Step 4: Calculate expected utility
Set u(0) = 0 and u(1) = 1.
The expected utility equals the fused positive-class belief.
